Field of the Invention The present invention relates to the field of geological exploration, and more particularly to a tool and method for the evaluation of chemical or other geophysical properties of soil. 2. Background Art Many of the existing hydrocarbon-producing regions of the world contain layers of unconsolidated sedimentary deposits. By definition, an unconsolidated sedimentary deposit is a relatively mobile grainy or granular formation, which may be composed of sand, clay, gravel, rock, or a combination thereof. The presence of unconsolidated sedimentary deposits could make a hydrocarbon reservoir a thin layer or pay zone, which may exist beneath overlying more structurally consolidated formations. The unconsolidated sediments could also contain significant quantities of petroleum. However, the presence of unconsolidated deposits can render evaluation of the potential for oil and gas production difficult. Injection wells and production wells have been used to explore and produce hydrocarbons from hydrocarbon-bearing formations. The targets for such exploration and production activities are generally the pore spaces or conduits, which are typically small in size, filled with hydrocarbons, and separated by impervious rock zones of the shale formation. To evaluate the fluid potential in the pore spaces, an accurate determination of the permeability of the rock zones is necessary. Techniques to evaluate permeability of the rock zone surrounding a wellbore in the production zone are known in the art. However,
